# 1 Overview

- 2 In this supplementary material, we present additional details and results to complement the main
- 3 manuscript, "See, Point, Fly: A Learning-Free VLM Framework for Universal Unmanned Aerial
- 4 Navigation" (hereafter referred to as the main submission or the main paper).
- 5 Section 2 elaborates on our proposed SPF (See, Point, Fly) framework, as detailed in the main
- 6 submission. Section 3.1 outlines task specifications, evaluation protocols, and provides example
- 7 prompts (Table 1) for simulated and real-world tasks. Section 3.2 details key implementation pa-
- 8 rameters, including adaptive scaling, VLM backend, control architecture, and latency. Section 3.3
- 9 directs the reader to demonstration videos of qualitative results. Section 3.4 presents an ablation
- study on our adaptive step-size controller, including setup, quantitative results (Table 2), and visual
- examples (Figure 1).
- 12 This supplementary material aims to provide a deeper understanding of our methodology (presented
- 13 in the main paper), experimental rigor, and key component benefits. Our video viewer webpage
- 4 attached along with this supplementary material also provides a comprehensive task demo for each
- 15 type of real-world and simulator tasks.

## 6 2 Method Details

#### 17 2.1 Reactive Control Loop Execution

- Input Variables: Given the structured VLM output  $O_t = \{U, V, d_{\text{adj}}\}$ , as described in the main
- paper. We transfer (U, V) into normalized value  $(U_{\text{norm}}, V_{\text{norm}})$ .
- Position Calculations: We use  $U_{\text{norm}}$  and  $V_{\text{norm}}$  to calculate the desired 3D displacement vector
- 21  $(S_x, S_y, S_z)$ . Where  $\alpha$  and  $\beta$  are the camera's horizontal and vertical half field-of-view angles,
- 22 respectively. These calculations follow the pinhole camera model detailed in the main submission
- 23 (see Section 3.3, Eq. 2 of the main paper for the specific formulation used).

$$S_x = U_{\text{norm}} \cdot d_{adj} \cdot \tan(\alpha), \quad S_y = d_{\text{adj}}, \quad S_z = V_{\text{norm}} \cdot d_{adj} \cdot \tan(\beta)$$

- Control Parameters: We use the 3D displacement vector  $(S_x, S_y, S_z)$  to calculate the UAV control
- primitive displacement:  $(\Delta\theta, \Delta \text{Pitch}, \Delta \text{Throttle})$ . The derivation of these control primitives from
- 26 the 3D displacement vector is detailed in the main submission (see Section 3.4 and Figure 3c of the
- main paper for the specific formulation used).

$$\Delta \theta = \tan^{-1} \left( \frac{S_x}{S_y} \right), \quad \Delta \text{Pitch} = \sqrt{S_x^2 + S_y^2}, \quad \Delta \text{Throttle} = S_z$$

Duration Calculations: Afterwards, we use  $(\Delta\theta, \Delta \text{Pitch}, \Delta \text{Throttle})$  and Pre-defined speed  $(P_{\text{yaw}}, P_{\text{pitch}}, P_{\text{throttle}})$  to calculate the Duration of each primitive  $(D_{\text{yaw}}, D_{\text{pitch}}, D_{\text{throttle}})$ .

$$D_{
m yaw} = rac{\Delta heta}{P_{
m yaw}}, \quad D_{
m pitch} = rac{\Delta 
m Pitch}{P_{
m pitch}}, \quad D_{
m throttle} = rac{\Delta 
m Throttle}{P_{
m throttle}}$$

30 Duration formula:

$$Duration = \frac{\Delta Distance}{Predefined\_Speed}$$

## 2.2 UAV Command Queue Implementation

Finally, we send enqueued rc commands to the UAV using a Python SDK (specifically DJITelloPy [1]).

```
# send_rc_control(roll, pitch, throttle, yaw_rate)
35
36
   # Yaw control
37
   def yaw(Pyaw, Dyaw):
38
       action_queue.append(send_rc_control(0, 0, 0, Pyaw))
39
       time_sleep(Dyaw)
40
       action_queue.append(send_rc_control(0, 0, 0, 0)) # Stop yaw rate
41
42
43
   # Pitch control
   def pitch(Ppitch, Dpitch):
44
       action_queue.append(send_rc_control(0, Ppitch, 0, 0))
45
       time_sleep(Dpitch)
46
       action_queue.append(send_rc_control(0, 0, 0, 0)) # Stop pitch rate
47
48
            / reset pitch
49
   # Throttle control
50
   def throttle(Pthrottle, Dthrottle):
56
       action_queue.append(send_rc_control(0, 0, Pthrottle, 0))
52
53
       time_sleep(Dthrottle)
<del>54</del>
       action_queue.append(send_rc_control(0, 0, 0, 0)) # Reset throttle
```

#### 56 Annotations

58

61

- 1. (U, V): 2D waypoint
  - 2.  $(d_{adi})$ : Adaptive step size
- $U_{\text{norm}}, V_{\text{norm}}$ : Normalized 2D waypoint
- 4.  $(S_x, S_y, S_z)$ : 3D displacement vector
  - 5.  $(\alpha, \beta)$ : camera's (horizontal FOV, vertical FOV), where FOV is field-of-view angle
- 6.  $(\Delta \theta, \Delta \text{Pitch}, \Delta \text{Throttle})$ : UAV control primitive displacements
- 7.  $(P_{\text{yaw}}, P_{\text{pitch}}, P_{\text{throttle}})$ : Pre-defined speed of each primitive
- 8.  $(D_{\text{yaw}}, D_{\text{pitch}}, D_{\text{throttle}})$ : Duration of each primitive

# **5 3 Experimental Details**

### 66 3.1 Task Specifications and Evaluation Protocols

- 67 Task outcomes are classified as Success or Failure. A trial is a Failure if the UAV collides or if, at
- the task's completion, the target is not visible within the drone's egocentric camera view. A trial is

a Success if, without collision, it has completed the specific task as the prompt requested (e.g., fly

through the building), or if the target is clearly visible in the final egocentric view and the drone

71 is positioned within 1 meter (real-world) or 1-5 meters (simulator) of the target. These criteria are

consistent with common evaluation practices in the AVLN benchmarks (e.g. [2, 3, 4, 5]).

73 A comprehensive table of examples of prompts (Table 1) is provided to illustrate the detailed in-

<sup>74</sup> structions for simulated and real-world tasks.

## 3.2 Implementation Details

Our system uses an adaptive scaling mechanism (detailed in the main paper, Section 3.2) with param-

77 eters s = 10, L = 10,  $d_{min} = 0.1$ m and p = 1.8. The control architecture operates asynchronously

78 with VLM inference at  $\approx 0.3 \sim 1$  Hz and low-level commands at  $\approx 10$  Hz, resulting in an end-

to-end latency of  $\approx 1.5 \sim 3$  seconds, primarily due to VLM inference time. Unless otherwise

specified, all experiments use Gemini 2.0 Flash [6] as the VLM backend.

## 81 3.3 Qualitative Videos

82 The qualitative results of our experiments are provided as demonstration videos in the exp\_results

directory of the supplementary materials. For convenient viewing, a video viewer webpage is in-

cluded in the same folder. By opening index.html in any modern web browser, the videos cor-

85 responding to the various tasks and scenarios discussed in the paper can be easily browsed and

viewed. This interface is intended to facilitate the evaluation of our approach and visually support

87 the findings presented.

# 3.4 Experiment Setup of Adaptive Travel Distance Scaling

89 To assess our adaptive step-size mechanism (Main Paper, Sec. 3.2), we conducted a real-world

90 ablation study comparing our Adaptive Step-Size Controller against a fixed baseline. The experi-

91 ments utilized a DJI Tello EDU drone, controlled via DJITelloPy [1] using low-level rc velocity

92 commands. Three distinct tasks, designed to test long-horizon planning and reasoning (detailed in

Table 2 and Figure 1), were each executed 5 times per controller configuration for robust compari-

94 son.

98

99

75

84

88

Table 2: Fixed vs. Adaptive Step-Size Controller performance on three real-world tasks. Metrics are Success Rate (SR) and Completion Time (Compl. time: start to finish). The adaptive controller significantly reduces completion times while maintaining or improving SR against the fixed baseline.

Prompt	Controller type	Compl. time	SR (%)
Fly to the cones and the next.	Fixed	61.00s	100
	<b>Adaptive</b>	<b>28.00s</b>	<b>100</b>
I'm thirsty. Find something that can help me.	Fixed	50.25s	80
	<b>Adaptive</b>	<b>35.20s</b>	<b>100</b>
It's raining. Head to the comfiest chair that will keep you dry.	Fixed	47.00s	100
	<b>Adaptive</b>	<b>30.00s</b>	<b>100</b>

The results in Table 2 show that the adaptive controller significantly reduces task completion times while maintaining or improving success rates (SR). For instance, in the task "Fly to the cones and the next." the completion time was more than halved (61s to 28s) with 100% SR. For "I'm thirsty.

Eind consoling that are halo we? the adoptive controlled decreased the consolition time (50.25) to

Find something that can help me.", the adaptive controller decreased the completion time (50.25s to

35.20s) and improved the SR from 80% to 100%. The "It's raining..." task also saw a substantial

time reduction (47s to 30s) with 100% SR. These findings confirm the efficacy of the adaptive mechanism in enhancing operational efficiency and reliability in complex real-world settings.

mechanism in enhancing operational efficiency and reliability in complex real-world sett

Long Horizon Reasoning I

Reasoning II

Figure 1: Visual examples of the real-world scenarios for the tasks (from left to right): Long Horizon ("Fly to the cones and the next."), Reasoning I ("I'm thirsty. Find something that can help me."), and Reasoning II ("It's raining. Head to the comfiest chair that will keep you dry."). These images depict the types of environments and objectives the UAV encountered during the ablation study evaluating the adaptive step-size controller.
